Skillomate | Additional testing and fixes

27 October 2026 - Comparison with the previous local version

Three checkout error-recovery issues were identified and fixed. Testing used local browser API fixtures for OTP, payment and handoff. No real OTP was sent, mandate created, or production deployment performed.

Issue	Before	After
Storage restrictions	A blocked sessionStorage write stopped checkout before payment preparation, even if localStorage worked.	Storage writes and cleanup fail independently; local storage fallback remains usable. Both blocked providers no longer crash the current flow.
Sandbox signup redirect	A successful local sandbox handoff used the production signup origin.	Development uses the matching local app on port 5173. Explicit app-origin configuration still takes priority. Production defaults remain unchanged.
Configuration recovery	A transient configuration failure required a full page reload.	Retry checkout configuration reloads and validates server pricing; renewal consent resets before continuing.

Verification results

Backend regression: 859/859 passed (previous round: 853/853). Six added tests cover storage provider failures, expired persisted sessions, and environment-correct signup handoff. Marketing TypeScript check and complete web/marketing production build passed. Diff whitespace check passed.

Browser: four new scenarios passed: session storage blocked, both storage providers blocked, failed configuration followed by retry, and successful sandbox handoff to localhost signup. Renewal consent remains required and one checkout request is issued per tested submission.

Web route smoke checks: Home, Courses, Pricing, Login, Signup, Dashboard and About. All seven rendered meaningful content without JavaScript exceptions or horizontal overflow at 390 x 844. Dashboard redirected unauthenticated access to Login. Configuration recovery was also checked at 1365 x 900.

Remaining limitations

Real PhonePe sandbox mandate approval, signed webhook delivery, renewal, cancellation and entitlement activation remain blocked by missing provider credentials and public callback configuration. Google Play license testing and iOS native runtime remain unverified. Fixture success is not proof of a successful provider payment.
